Preface

The material in this report is based on findings from the Minnesota Household Survey, a statewide survey conducted in April, 1977. This survey was designed to provide current information on a broad range of demographic and labor force characteristics of the Minnesota population. It was conducted cooperatively because of the common needs and interests of several participants: the Office of State Demographer in the State Planning Agency, the Division of Vocational Education in the Department of Education, the Office of Statewide CETA Coordination in the Department of Economic Security, and the Environmental Quality Board's Copper-Nickel Project. The survey's principal aims were to:

1. Obtain an updated set of characteristics of the population of Minnesota. The last full set of characteristics is from the 1970 Census.
2. Learn more about people's perceptions of their needs for job training, in order to help plan for vocational education.
3. Obtain more information about the labor force, in order to assess employment and unemployment issues facing Minnesota.
4. Develop an updated set of characteristics for the East Range (from Virginia to Ely), in order to help meet the state's commitment to assess the impact of potential copper-nickel mining in northeast Minnesota.

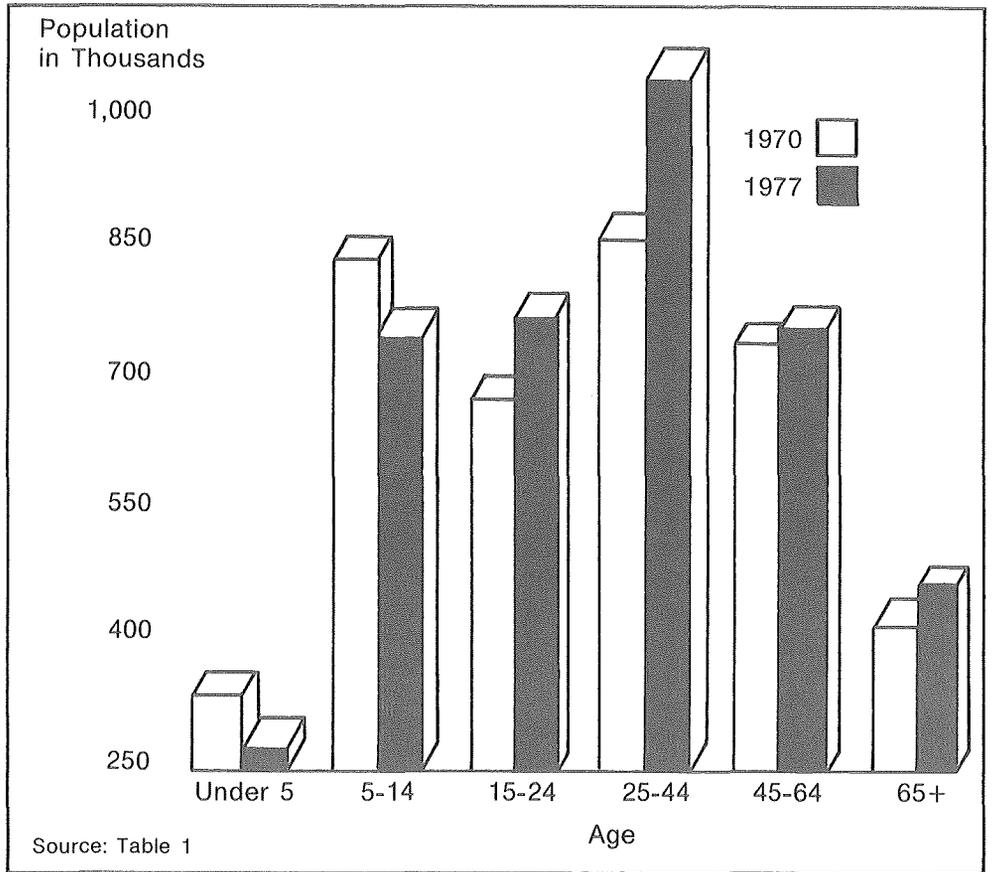

The survey consisted of a statewide sample of approximately 4,530 households. Sample results have been expanded to agree with independent estimates of the population. The number of cases is sufficient to develop estimates of general demographic characteristics for the state, the seven-county Twin Cities metropolitan area (Region 11), and the balance of the state.

As in all sample surveys, the data in this report are subject to sampling variability and errors of response, including under-reporting and non-reporting. A detailed explanation appears in Appendix II.

This is the fourth publication based on Minnesota Household Survey data. The other reports, "Housing in Minnesota, 1977", "Educational Attainment in Minnesota, 1977" and "Minnesota Household Characteristics, 1977" are available upon request from the Office of State Demographer.

Figure 1
Minnesota Population by Age, 1970 and 1977

Highlights

Minnesota's population grew by 4 percent from 3,805,000 in 1970 to 3,962,000 in 1977.¹ Recent declines in the number of births and the movement of the post-war "baby-boom" generation into adulthood have caused the size of some age groups to increase sharply and others to decrease over the past seven years.

This report covers the age and sex composition of the Minnesota population. Highlights of the 1970 to 1977 period are as follows:

- The population 25 to 44 years old grew the fastest, increasing by 159,000 or 19 percent.
- In contrast, the 45 to 64 year-olds (many of whom were born during the low birth-rate years of the 1920s and 1930s) increased by only two percent.
- The pre-school age population (under 5 years) declined by 58,000 or 18 percent. The population 5 to 14 years decreased by 92,000 or 11 percent.
- The decline in the number of children under 5 years old was greater in the Twin Cities metropolitan area (Region 11) than in the balance of the state, 26 percent compared with 8 percent.²
- The elderly (65 years and over) increased by 45,000 or 11 percent.
- The dependency ratio (the number of persons under 18 and over 64 years per 100 persons 18 to 64 years) dropped from 89 in 1970 to 75 in 1977.
- The increase in the number of adults 25 to 44 years and 65 years and over has been greatest outside the Twin Cities metropolitan area.
- Minnesota continued to experience slight net outmigration in the 1970s of 10,000 persons or -0.2 percent.
- As in the 1960s, the largest component of outmigration is among young adults 15 to 24 years old. The net outmigration rate of males in this age group has remained around 10 percent, while the female net migration rate changed from +0.5 percent in the 1960s to -4 percent in the 1970s.
- The population grew most rapidly outside the Twin Cities metropolitan area: 6 percent in the balance of the state compared with 2 percent in the Twin Cities metropolitan area. Net immigration contributed 46,000 to population growth in the balance of the state contrasted with the net outmigration of 56,000 from Region 11.

1. All 1977 data in this report are for April. Data in *Population Estimates for Minnesota Counties, 1977* are preliminary estimates for July 1, 1977.

2. Region 11 is the seven-county Twin Cities metropolitan area — Anoka, Carver, Dakota, Hennepin, Ramsey, Scott and Washington Counties. The balance of the state includes all other Minnesota counties.

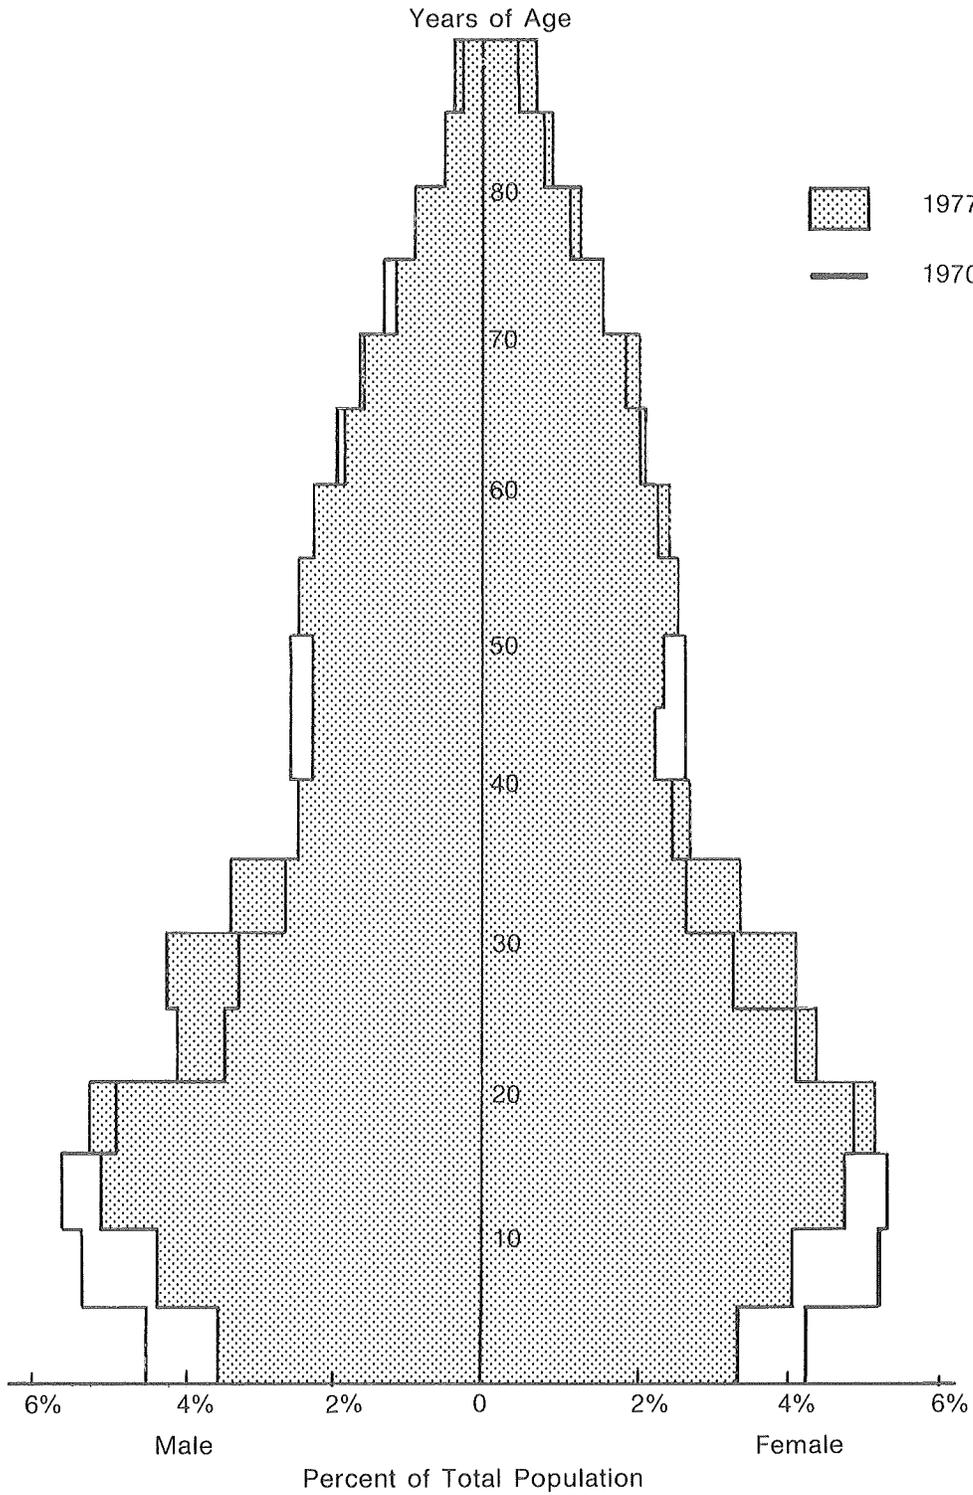

Population Characteristics By Age, 1970 and 1977

Appendix I

Definitions and Explanations

Age

The age classification is based on the age of the person at the person's last birthday. Age data in this report have been adjusted for "age-heaping" (that is, the distributional problems resulting from misreporting of age), and include estimates of group quarters population. See Appendix II for a detailed explanation.

Balance of the State

Balance of the state refers to one of two major geographic divisions for which data are presented in this report. The balance of the state includes 80 of the state's 87 counties; it does not include the seven-county Twin Cities metropolitan area defined as Region 11 (Anoka, Carver, Dakota, Hennepin, Ramsey, Scott and Washington Counties). The balance of the state is further divided into two areas: Region 3 (Aitkin, Carlton, Cook, Itasca, Koochiching, Lake and St. Louis Counties) and the remainder of the state.

Dependency Ratio

The standard measure of dependency is based on the assumption that persons 18 to 64 years old are the "productive" segment of the population and persons under 18 years and 65 years and over are the "dependent" segment.

The formula is as follows:

$$\text{Dependency ratio} = \frac{\text{Dependent segment}}{\text{Productive segment}} \times 100$$

This ratio is a measure of the dependency load the productive population must bear.

The child dependency ratio is the number of persons under 18 years per 100 persons 18 to 64 years; the aged dependency ratio is the number of persons 65 years and over per 100 persons 18 to 64 years.

Migration

Migration data in this report are presented in two ways: net migration numbers and net migration rates.

Net migration is the difference between the expected number of survivors from a preceding census ("expected population") and the estimated or enumerated population at a later date. Net migration between 1970 and 1977 is the difference between the estimated state population of 1977 based on results from the Minnesota Household Survey and the 1977 expected state population (survived from 1970). The net migration rate results from dividing net migration by the expected population.

Region 3

Region 3 comprises the seven-county area of northeastern Minnesota — Aitkin, Carlton, Cook, Itasca, Koochiching, Lake and St. Louis Counties.

Region 11

Region 11 is the seven-county Twin Cities metropolitan area — Anoka, Carver, Dakota, Hennepin, Ramsey, Scott and Washington Counties.

Remainder of the State

Remainder of the state is the portion of the state excluding Region 3 (Aitkin, Carlton, Cook, Itasca, Koochiching, Lake and St. Louis Counties) and Region 11 (Anoka, Carver, Dakota, Hennepin, Ramsey, Scott and Washington Counties).

Appendix II

Source and Reliability of the Estimates

Introduction

The estimates in this report are based on data collected during April 1977 through direct interviews with persons living in housing units in Minnesota. Weighted sample results have been adjusted for "age-heaping" and expanded to agree with independent estimates of the population made by the Office of State Demographer using procedures described below. Independent estimates of the group quarters population were added to develop the final age-sex estimates of the total population.

Source of the Data

Approximately 4,530 occupied housing units were selected for interview in the Minnesota Household Survey. Within each household, a responsible person aged 16 or older was interviewed for demographic characteristics of all household members. From the listing of household members 16 years of age and over, one of them was objectively designated as the respondent for an in-depth interview on labor force status and interest in job training.¹ No substitution was made even if, after repeated calls, no one was at home, or the designated respondent for the individual interview was not at home or refused to be interviewed. Approximately 96 percent of the households were interviewed for household data; 98.8 percent of these were interviewed for individual labor force data. Of the 4,661 persons eligible for the short self-administered job-training questionnaire, 78 percent responded.

The Sample

The Minnesota state sample is designed to produce estimates of demographic and socio-economic characteristics for Minnesota's household population. The sample design is modeled after the proven multi-stage area probability designs which have long been used at the national level by the U.S. Bureau of the Census and University of Michigan's Survey Research Center.

The selection process is performed in two stages and assigns every year-round housing unit in Minnesota an equal probability of being selected for interview. In the first stage of selection, sample counties are chosen with a probability proportional to number of year-round housing units. Groups of year-round housing units referred to as "clusters" are then selected from each sample county.

The resulting sample is termed "complex" and is not "random" in the true sense of the term. Nonetheless, the sample does meet the statistically more important criterion of assigning to each element of the population an equal probability of selection. In selecting the year-round housing unit with equal probability, all items uniquely associated with the selected unit are also chosen with equal probability (children, telephones, microwave ovens, etc.).

Sources of Error

Sample data are subject to errors arising from several sources. Among these are noncoverage, response and reporting errors, nonresponse, coding error, and sampling error.

- **Noncoverage.** A bias is introduced by excluding persons living in institutions or group quarters from the data collection process. For purposes of this report, independent estimates of group quarters population have been included. A very small bias may exist because of failure to identify all housing units in the selected sample cluster.
- **Response and reporting error.** Variations in interviewers' wording of questions or faulty questionnaire design may cause errors by interviewers, respondents, or both. Although this study's interviewers were chiefly temporary workers, the majority were persons with survey experience. These interviewers participated in an intensive two-day training session, preceded by a home-study assignment. Moreover, timely editing of the completed

questionnaires, supervisors' observation during enumeration, and a systematic reinterview by supervisory staff of part of their assignments permitted the interviewers to correct any errors or deficiencies.

In spite of these controls, interviewers may not always have asked the questions in the prescribed fashion. This factor, in addition to the unwillingness of some respondents to report accurately, may result in some errors or lack of uniformity in the results.

Of particular concern in age data is "age-heaping", that is, the well-documented distribution problem occurring as the result of the misreporting of age.² The concentration of people at regular intervals indicates the strong preference or avoidance shown for certain numbers. For example, preference is noticed for certain ages of special legal or cultural significance such as the age of eligibility to receive retirement pensions. The ages most affected in the Minnesota Household Survey are 39 to 40 years, 49 to 50 years, 59 to 60 years, 63 to 67 years and other decade or mid-decade intervals at ages over 65. Middle-age individuals tended to under-report age and persons 65 and older gave rounded numbers. In particular, women between the ages of 63 and 67 tended to report being 65 years old.

- **Nonresponse.** The Minnesota Household Survey enjoyed response rates in excess of 96 percent. Consequently, nonresponse bias should be virtually nonexistent for these data. The Vocational Education Supplement data with a 78 percent response rate has the potential for nonresponse bias depending on the assumptions one makes concerning the nature of the nonrespondent group.
- **Coding error.** The questionnaires used in this survey were almost entirely precoded, with appropriate

1. This procedure is described by Leslie Kish, "A Procedure for Objective Respondent Selection Within The Household", *American Statistical Association Journal*, September 1949, pp. 380-387.

2. George W. Barclay, *Techniques of Population Analysis* (New York, 1958), pp. 66.

responses being circled or recorded by the interviewer. Through a 100 percent check-coding process, detected errors were corrected. A 100 percent verification was also used throughout keypunching of the data. In addition, an elaborate computer editing process was designed to detect inconsistencies and inappropriate responses not found during the manual editing and coding stages.

Although there was close control of all phases of processing, some errors are inevitable in an operation of this type and magnitude. However, the net error is likely to be negligible.

- **Sampling Error.** With the described probability design used for this survey, sampling errors can be approximated from the sample itself. A measure of sampling variability indicates the range of difference that may be expected because only a sample of the population is surveyed.

Sampling error, which should be distinguished from bias, is composed of several factors. The majority of the error results from the distributional properties of the sample itself. A portion of the error in the sample data results from the variability among interviewers and coders.

Age-heaping Adjustment

To compensate for the age-heaping in the Minnesota Household Survey, the following technique was used. The technique assumes the sample response bias is restricted to localized segments of the age distribution and is not significant for broad age groups.

First, the sample distribution was smoothed to eliminate the pronounced age heaps which resulted from response bias. Single year of age data were aggregated into five-year categories which were lagged two years from the standard intervals (e.g., 3 to 7, 8 to 12, 13 to 17, etc.). The intervals span the age breaks where the most serious age-heaping or

under-reporting occurred. The totals of these lagged five-year groups were graduated back to single year of age using Beer's multipliers for polynomial graduation.³ The smoothed single year of age sample distribution was reaggregated into the standard five-year categories.

Next, the sample and graduated sample results were averaged for the five-year age cohorts from 20 years to 85 and over. The averaging of these two forms of the sample data is an attempt to smooth out the points of age-heaping and yet retain the true population fluctuations which may have been captured in the sample results.

Expansion to Total Population

The adjusted sample results for the five-year cohorts were expanded to independent estimates of the total household population for three geographic divisions: the seven-county Twin Cities metropolitan area (Region 11), northeastern Minnesota (Region 3) and the remainder of the state.⁴ Estimates of the non-household (group quarters) population, derived independently using total 1977 group quarters estimates and 1970 Census distributions, were added to produce five-year cohort estimates for the total population for each region.

The calculations were as follows for each region:

$$\text{PopT}_x = \text{PopH}_x + \text{PopGQ}_x$$

$$\text{PopH}_x = K \cdot N_x$$

$$\text{PopGQ}_x = r_x \cdot \text{PopGQ}$$

Where:

PopT_x = Total population estimated for any five-year cohort (x)

PopH_x = Household population estimate for any five-year cohort (x)

PopGQ_x = Group quarters population estimate for any five-year cohort (x)

N_x = adjusted sample results for any five-year cohort (x)

K = $\frac{\text{Independent household population estimate}}{\text{Total of adjusted sample results}}$

r_x = Proportion of 1970 group quarters population in five-year cohort (x)

The resulting population estimates were divided into male and female categories using 1970 age-sex ratios for each five-year age group and controlled to independent estimates for the 0 to 4, 5 to 24, 25 to 44, 45 to 64, and 65 and over age subdivisions as well as a final control based on 1970 sex ratios. These controls were linear, adjusting each five-year age-sex estimate in proportion to its size relative to its respective control subdivision.

The five-year age-sex estimates for Minnesota were formed by adding the final estimates for the three regional units. This post-stratified estimation of the state age-sex distribution reduced the variance of these estimates over the standard unstratified product.

This report presents these data aggregated into ten-year age-sex groups for each region (see Tables 4 and 5). The aggregations were made because of continued evidence of age-heaping in the five-year age-sex groups. Ten-year age group data should serve the purposes of most users.
